Abstract: Stakeholders in the construction industry work towards obtaining optimal concrete mixes with an aim of producing structures with the best compressive strength. In many instances, Kenya has witnessed collapse of buildings leading to death and huge financial loses, which has been associated largely to poor concrete mixes. This paper aims at evaluating the I-optimal designs for a concrete mixture experiment for both Equally Weighted Simplex Centroid Axial Design and Unequally Weighted Simplex Centroid Axial Design, based on the second-degree Kronecker model. Optimality tests are performed to locate the optimum values of a design. In various studies, I-optimality has been shown to be among the best criteria in obtaining the most optimal outcomes. In this study, Response Surface Methodology is applied in evaluating I-optimal designs, which are known to minimize average or integrated prediction variance over the experimental region. I-optimality equivalence conditions for the inscribed tetrahedral design and for the concrete experiment model are identical with the boundary points, mid-face points and the centroid, denoted by \( \eta_2, \eta_3 \) and \( \eta_4 \) respectively. Equally, Weighted Simplex Centroid Axial Design proved to be a more I-efficient design than the Unequally Weighted Simplex Centroid Axial Design for both the tetrahedral design and the concrete model, with 87.85% and 79.54% respectively. The optimal response surface occurred in the region of the I-optimal designs. The Kronecker model derived from the concrete mixture experiment proved effective and efficient in describing the observed results.

Keywords: I-Optimality, Tetrahedral, Efficiency, Equivalence, Average Prediction

1. Introduction
In the general mixture problem, the measured response is assumed to depend only on the proportions of the ingredients present in the mixture and not on the amount of the mixture according to [2]. The mixture ingredients \( t_i, i = 1, 2, \ldots, m \) are such that \( t_i \geq 0 \). The experimental region is given by the probability simplex \( T_m = \{ t = (t_1, \ldots, t_m)' \in [0,1]^m; \sum_{i=1}^{m} t_i = 1 \}, t \in T_m \).

The objectives of the analysis of mixture data are to fit a proposed model for describing the shape of the response surface over the simplex factor space, and to determine the roles played by the individual components also alluded is that the same analysis may achieve these two objectives at once as said by [2]. Axial designs are defined as the designs with interior points \( x_i = 0, x_j = \frac{1}{1-q}, \forall \ j \neq i \) and \( x_i = 1, x_j = 0, \forall \ j \neq i \), which contains the points of the form \( \left[ \frac{1+(q-1)\Delta}{q}, \frac{1-\Delta}{q}, \ldots, \frac{1-\Delta}{q} \right] \) and its permutations \( \frac{1-\Delta}{q} < \Delta < 1 \), as described by [13].

An optimality criterion is one, which summarizes how good a design is, and it is maximized or minimized by an optimal design. I-optimality criterion is an information-based criterion, and unlike the D-optimal designs the I-optimal designs are not frequently used, as was noted by [12]. The D-optimal designs aims at precise model estimation while the I-optimal designs aims at obtaining precise predictions. For mixture experiments, the focus is to find certain responses for any given components proportions formulations, with an aim of obtaining the optimal responses from optimal settings with the best precision. D- and G-optimal designs for four ingredient mixture, were evaluated by [9]. This paper evaluates the same D-and
G-optimal designs with I–optimality criteria for a concrete mixture experiment to obtain precise predictions on outcomes.

2. Methodology

Some study that applied the Kiefer’s functions as optimality criteria to evaluate the designs in three degree Kronecker model mixture experiment for non-maximal subsystem of parameters was by [7]. This study chose I-optimality also known as the Q-optimality and as IV-, V-optimality as called

$$E(Y_j) = f(t)\cdot \theta = (t \otimes t')\cdot \theta = \sum_{i=1}^{m} \theta_{ij} t_i^2 + \sum_{i=1}^{m} \sum_{i<j} (\theta_{ij} + \theta_{ji}) t_i t_j$$

(1)

$$E(Y) = \theta_{11} t_1^2 + \theta_{22} t_2^2 + \theta_{33} t_3^2 + \theta_{44} t_4^2 + \theta_{12} t_1 t_2 + \theta_{13} t_1 t_3 + \theta_{44} t_4 t_4 + \theta_{23} t_2 t_3 + \theta_{24} t_2 t_4 + \theta_{34} t_3 t_4$$

(2)

Two weighted designs for four components namely; Equally Weighted Simplex Centroid Axial Design (EWSCAD) and Unequally Weighted Simplex Centroid Axial Design (UWSCAD) were used to compare the I-optimality conditions for the concrete experiment model, which were evaluated against the I-optimality conditions of the inscribed tetrahedral design.

Direct search for optimum designs could be difficult because it depends on the nature of response function, criterion function and the experimental region as was explained by [14].

The I-optimal criteria develops designs that minimizes the average or integrated prediction variance over the experimental regions given in (3) as given by [1].

$$Average\ variance = \frac{\int_{dx} f'(x)M(x)^{-1}f(x)}{\int_{dx}}$$

(3)

$$B = \int_{x=1}^{x=p} X_1 X_2 ... X_q \; dx,1, dx_2, ..., dx_p$$

(4)

$$L_{ij} = \frac{\prod_{\gamma=1}^{\gamma=q}p_i} {\prod_{\gamma=1}^{\gamma=q}p_i+r_{ij}-1}$$

(5)

Average variance = $tr[M^{-1}L]$ and $L = \Gamma(q)B$. $L$ is the moment matrix since the elements are moments of a uniform distribution on the experimental region $S_{a-1}$, and $M$ is the information matrix of the full model. $B$ is the matrix given as

$$M = \left[ \begin{array}{cccccccc} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{array} \right]$$

(6)

Since the information matrix $M(\xi)$ in (3) is constant as far as the integration is concerned, the formula for the average variance can also be expressed as (4).

$$\int_{dx} f'(x)M(\xi)^{-1}f(x)\; dx = tr[M(\xi)^{-1}f'(x)f(x)]$$

(7)

Prediction variance can be rewritten as (5) as was stated by [11].

$$Ave.\ variance = \frac{1}{\int_{dx}}trace[M(\xi)^{-1}B]$$

(8)

The matrix $B$ was obtained by the integral

$$B = \int_{x=1}^{x=p} X_1 X_2 ... X_q \; dx,1, dx_2, ..., dx_p$$

(9)

$\Gamma(q) = K = (q - 1)!$ and $M = X'AX$, where $X = [f(t_1), ... , f(t_p)]$ is the $p \times p$ matrix model corresponding to $p$ points of the simplex centroid design. $A = \text{diag}(r_1, r_2, ..., r_q)$, $r_1, ..., r_q$ are the weights of the different design points.

$$Average\ Variance = \frac{1}{\int_{dx} dt} tr[M^{-1} \int_{dx} f(t) f'(t) dt]$$

(10)
The focus of this study was the subsystem of interest, hence the average variance was obtained by

\[ \text{Ave. variance} = \text{tr}[C^{-1}L] \]  

(11)

C is the information matrix of the subsystem of interest; this was represented by equations (18) and (19) for EWSCAD and UWSCAD respectively in [9].

The general equivalence theorem provides a methodology to check the optimality of a given continuous design, for any convex and differentiable design optimality criteria.

A continuous design with information matrix M for the full convex and differentiable design optimality criteria. To check the optimality of a given continuous design, for any model is I-optimal if and only if

\[ f'(t)M^{-1}LM^{-1}f(t) \leq \text{tr}(M^{-1}L) \]  

(12)

As indicated by [1].

The subsystem of interest design points in the experimental region are I-optimal if and only if

\[ f'(t)C^{-1}LC^{-1}f(t) \leq \text{tr}(C^{-1}L) \]  

(13)

Efficiency of designs enables to find the better performing designs. Comparing the average variances of prediction and \( \hat{C} \), the boundary points were better than the designs obtained from interior support points as expressed by [15].

I-efficiency larger than 100% indicates that \( \hat{C} \) is better than \( C \) in terms of the average prediction variance. A study that obtained the values of the desired optimal design with respect to their corresponding information matrices, discovered that the D-A-E-G optimality designs at the boundary points were better than the designs obtained from interior support points as expressed by [15].

3. Results and Discussions

The integrals of the \( 10 \times 10 \) matrix are as shown in set of equations (15). The components are represented by \( i,j,k,w = 1,2,3,4 \), while \( n \) and \( m \) represent the rows and columns of the moment matrix \( L \), the constant \( K = 6 \). The matrix \( L \) is a symmetric matrix along the main diagonal.

\[ M_{nn} = K \int t_i^4 dt_i = \frac{314!}{(4+4-1)!} = \frac{1}{37} \times n = n = 1,2,3,4. \]

\[ M_{nn} = K \int t_i^2 t_j dt_i dt_j = \frac{1}{210}, (i \neq j), (n \neq m) = 1,2,3,4. \]

\[ M_{nm} = K \int t_i^2 t_k dt_i dt_k = \frac{1}{140}, i \neq j \]  

(15)

\( (n,m) = \{(1,5), (1,6), (1,7), (2,5), (2,8), (2,9), (3,6), (3,8), (3,10), (4,7), (4,9), (4,10)\} \)

\[ M_{nm} = K \int t_i^2 t_j dt_i dt_j = \frac{1}{140}, i \neq j, \]  

\( (n,m) = \{(1,8), (1,9), (1,10), (2,6), (2,7), (2,10), (3,5), (3,7), (3,9), (4,5), (4,6), (4,8), (5,6), (5,7), (5,8), (5,9), (6,7), (6,8), (6,10), (7,9), (7,10), (8,9), (8,10), (9,10)\}. \)

The summarized workings in (15) are as shown in the moment matrix (16).

\[ M_{nm} = K \int t_it_j t_k dt_i dt_j dt_k = \frac{1}{840}, i \neq j \neq k, w = 4 (n,m) = (5,10), (6,9), (7,8), n \neq m. \]

For optimality to suffice, LHS of the I-optimality equivalence theorem of each design point should be less or equal to \( \text{trace}[C^{-1}L] = 73.9209 \) and \( \text{trace}[C^{-1}_wL] = 64.9382 \) for EWSCAD and UWSCAD respectively. The LHS of the equivalence theorem given by \( f'(t)C^{-1}LC^{-1}f(t) \) and \( f'(t)L^{-1}C^{-1}L^{-1}f(t) \) respectively for each design points were given in tables 1 and 2 respectively.

### Table 1. I-optimality Equivalence Theorem for EWSCAD.

</tr>
</tbody>
</table>

The design points \( \eta_2, \eta_3 \), and \( \eta_4 \) for the two designs attained the optimality according to the equivalence theorem.
The I-efficiency given by the equation (14) was utilized to compare the efficiencies of the two designs namely the EWSCAD and UWSCAD. It showed that $I_{\text{eff}} = \frac{2.5.3^2}{2.5.3^2 + 1.0.4^2} = 0.8785$, meaning that the EWSCAD was a better design than the UWSCAD.

$$E(\bar{y}) = 23.41t_1^2 + 37.95t_2^2 + 37.31t_3^2 + 28.39t_4^2 + 34.93t_1t_2 + 53.46t_1t_3 + 60.53t_1t_4 + 38.83t_2t_3 + 48.34t_2t_4 + 59.27t_3t_4 \quad (18)$$

Table 3 represents the ANOVA table for the model (18).

</tr>
</tbody>
</table>

The F calculated value is 2.10 and $F_{(0.1,9,25)} = 1.79$, this showed that the model estimates were significant meaning that compressive strength of concrete varied on the different combinations of the components.

A stationary point of a response surface may be obtained by use of Canonical analysis, where the regression model is transformed to a new co-ordinate system, but the most straightforward way is to examine a contour plot of the fitted model as indicated by [8]. The data obtained from the experiment for this study was presented using the contours and response surfaces.

The Figure 1 is the data boxplot that gives the descriptive statistics of the concrete experiment. It indicated that the median of the data is approximately 27.5 $N/mm^2$. It also shows that the reading 31.509 $N/mm^2$ is an outlier.

Figures 2, 3 and 4 shows the image, contours and the response surface respectively of one of the $4C_2$ outcomes of the experiment. It shows how compressive strength was affected due to water and cement interaction. At a constant ratio of 0.4 of cement there was a steep descent of compressive strength as water was increased.
The $L_2$ matrix (19) of the concrete experiment Kronecker model below was obtained by the use of the integrals summarized in (16) and the betas in the regression model (18).

The RHS I-Optimality values of the I-equivalence theorem for the Concrete model of UWSCAD were obtained from (20) the matrix $C_{\alpha}^{-1}L_2$. Where $C_{\alpha}^{-1}$ is the inverse of matrix (18) as done by [9].

The RHS of (13) for the Concrete model with equal weights was $AV = tr(C_{\alpha}^{-1}L_2) = 17,477.51$. The design points should be I-optimal if and only if $f'f(t)C_{\alpha}^{-1}L_2C_{\alpha}^{-1}f(t) \leq 17,477.51$.

The RHS of (13) for the Concrete Kronecker model with unequal weights was $AV = tr(C_{\alpha}^{-1}L_2) = 13,902.12$. The design points are I-optimal if and only if $f'f(t)C_{\alpha}^{-1}L_2C_{\alpha}^{-1}f(t) \leq 13,902.12$.

The concrete model has showed that the designs $\eta_2$, $\eta_3$, and $\eta_4$ achieved the optimality condition, for both the Concrete model of EWSCAD and UWSCAD as shown in [Table 4]. The efficiency of the two designs on the concrete experiment using (14) was, $I_{eff} = 13,902.12 \times 100 = 79.54\%$. EWSCAD turned out to more I-efficient than UWSCAD.

### 4. Conclusion

The results on I-optimality and efficiency for the inscribed tetrahedral design and the concrete experiment were identical.

Likewise, the RHS I-optimality values of the I-equivalence theorem for the Concrete model of UWSCAD were obtained. The matrix (21) which is $C_{\alpha}^{-1}L_2$ was obtained from (19) above and inverse of matrix $C_{\alpha}$ (19) of [9].

The design points $\eta_2$, $\eta_3$, and $\eta_4$, for the two designs and the experiment attained the same optimality conditions by use of the I-optimal equivalence inequality. EWSCAD was a more efficient design than UWSCAD. The response surface shown by figure 2 showed that the lowest line of descent also fell on the I-optimal design points. The $I$-optimality criterion being one that reduces average prediction variance, does optimize outcomes more than any other criteria does. For further studies, another simplex centroid axial design may be used to evaluate the same I-optimality conditions to create an experimental design, which would otherwise be evaluated for the same.
